Framework for teaching and learning informed shared decision making
Angela Towle, William Godolphin

Patients should be involved in making decisions about their health care. The ethical imperative of autonomy is reflected in legal trends that require a high standard of disclosure for informed consent, amounting to a principle of informed choice. Outcomes of care and adherence to treatment regimens improve when patients are more involved. Consumerism is part of the social spirit, and governments exhort citizens to take more responsibility.

Models of doctor-patient encounters that result in increased involvement of patients and that are informed by good evidence have been termed, for example, “informed patient choice” but do not describe the interactive process clearly. We use the term informed shared decision making to describe decisions that are shared by doctor and patient and informed by best evidence, not only about risks and benefits but also patient specific characteristics and values. It occurs in a partnership that rests on explicitly acknowledged rights and duties and an expectation of benefit to both.

We propose that a demonstrated capacity to engage in informed shared decision making is characterised by a set of necessary and sufficient competencies. By competencies we mean the knowledge, skills, and abilities that represent the instructional intents of a programme, stated as specific goals. They are a framework for teaching, learning, practice, and research.

Summary points

Competencies for the practice of informed shared decision making by physicians and patients are proposed

The competencies are a framework for teaching, learning, practice, and research

Challenges to putting informed shared decision making into practice are perceived lack of time, physicians' predisposition and skill, and patients' inexperience with making decisions about treatment
of what should be a coherent process and an accomplishment of any doctor-patient encounter in which a substantive decision is made about treatment or investigation for which reasonable choices exist. They are mainly related to communications skills, but at a higher level than those typically taught in medical schools and continuing medical education, where the emphasis tends to be on obtaining information from patients (diagnostics), breaking bad news, and health promotion. We present them with an intent of parsimony and coherence. The sequence is not intended to be prescriptive, nor do they describe verbal phrases or a check list of behaviours. The time and attention paid to the separate elements will vary with circumstances; they may occur over several encounters and will probably be iterative.

It seems logical that if informed shared decision making takes place in partnership then patients should bring certain abilities to the encounter. If the sole responsibility for informed shared decision making rests with physicians then we tend to perpetuate the paternalistic “doctor knows best” relationship. Others (such as a doctor’s nurse or receptionist and a patient’s spouse or parent) may also make important contributions to informed shared decision making. Although our work has mainly focused on the development of competencies for physicians, we have developed a preliminary set of complementary competencies for patients.

Methods

We performed a literature search using electronic databases (Medline, CINAHL, and HealthSTAR) and references listed in textbooks to produce a draft list of competencies. We then tested their validity in semistructured interviews with five family doctors, four patients, and three patient educators (health professionals whose role is to educate and counsel patients about their condition) who were identified by their peers as having good communication skills. We also tested the validity of the competencies in focus groups with cancer patients, diabetic patients, and patient educators.

Physician competencies

We defined a working set of eight competencies for physicians through the literature review, interviews, and focus groups (see box). The basic concepts inherent to informed shared decision making, and thus underlying the competencies, are partnership (competency 1), explicit dialogue (all, but especially 2 and 3), an informed patient (4 and 6) and physician (4 and 5), shared decision making (6 and 7), and completeness.¹

Partner

The defining characteristics of partnership derive from the models of mutual participation and contracts.¹⁶–¹² From the literature and our interviews and observations, we conclude that partnership

• Implies mutual responsibilities (both physician and patient have something to gain and contribute)
• Requires attention to, and explicit discussion about, the relationship
• Is dynamic and adapts to changing circumstances of either party

Competencies for physicians for informed shared decision making

1. Develop a partnership with the patient
2. Establish or review the patient’s preferences for information (such as amount or format)
3. Establish or review the patient’s preferences for role in decision making (such as risk taking and degree of involvement of self and others) and the existence and nature of any uncertainty about the course of action to take
4. Ascertain and respond to patient’s ideas, concerns, and expectations (such as about disease management options)
5. Identify choices (including ideas and information that the patient may have) and evaluate the research evidence in relation to the individual patient
6. Present (or direct patient to) evidence, taking into account competencies 2 and 3, framing effects (how presentation of the information may influence decision making), etc. Help patient to reflect on and assess the impact of alternative decisions with regard to his or her values and lifestyle
7. Make or negotiate a decision in partnership with the patient and resolve conflict
8. Agree an action plan and complete arrangements for follow up
   • Informed shared decision making may also:
     Involve a team of health professionals
     Involve others (partners, family)
     Differ across cultural, social, and age groups

• Can be initiated at any time, but takes time to develop; most encounters ought to provide opportunities for partnership building
• Is key to the other informed shared decision making competencies.

Explicitness

In the absence of explicit discussion, physicians make incorrect assumptions and unilateral decisions about patients’ information needs and preferences, and incorrectly assess their own information giving behaviour.¹³–¹⁵ A consistent theme in the literature is that patients want more information than they get, although studies on patients’ preferences for decision making show more variation. The obvious solution is to engage in an explicit
discussion. Preferences should be rechecked since needs vary over time and at different stages of illness. Some
decisions are inherently more difficult, and uncertainty
remains about the course of action to take—for example,
because of a lack of information about alternatives and
consequences, emotional distress, or perceived pressures
from others. Through discussion the physician may
help to clarify the existence, nature, and degree of these
uncertainties.

The informed patient
Patients bring information to the consultation that
needs to be shared. In relation to decision making
patients bring three perspectives to the problem: informa-
tion, expectations, and preference. Eliciting these
concerns, ideas, and expectations is at the heart of
patient-centred care (finding common ground) and
again needs to be done explicitly. The patients we
interviewed gave examples of how doctors make
assumptions and inaccurate guesses about patients’
concerns, and there is always the potential for misun-
derstanding. For example, a reassurance such as “It’s
nothing to worry about” may be interpreted as
ignoring important anxieties.

The informed physician
Physicians need to be able to find and evaluate current
evidence. Two points emerged from our interviews:
the patients assumed that this is what doctors do
already, and they wanted physicians to consider all
options available (not just drugs) including those
suggested by the patient. Alternative and complementa-
tory therapies are a challenge. The patients noted that
physicians are often not open to or informed about
such therapies (“Saying ‘It can’t do you any harm’ is no
discussion”), and there is rarely any evidence about
their efficacy. Even if these are not included as valid
choices they cannot be ignored. Many patients
contemplate and use them, and only a minority
disclose this to physicians.

Shared decision making
A rich and complex literature on decision making,
decision analysis, communication of risk information,
and framing effects underlies this competency. Theories
about decision making suggest that people
do not have stable and pre-existing beliefs about self
interest but construct them in the process of eliciting
information or deciding a course of action. The way
information is provided by the physician is therefore
crucial in assisting patients to construct preferences.

Practising the competencies for informed shared
decision making should lead to an agreed decision.
Problems may arise if there is no obvious best option
(for example, because of lack of good evidence) or
disagreement about the best option. Physician and
patient are then in conflict, and a solution needs to be
negotiated. If decision making is not explicit, conflict
may go unrecognised by the physician, with conse-
quences such as patient dissatisfaction and non-
adherence with treatment. In the context of informed
shared decision making, we take negotiation to mean
“a back and forth communication designed to reach an
agreement when you and the other side have some
interests that are shared and others that are
opposed.”

Completeness
Informed and shared decisions do not just happen.
Both parties need to be clear on what decision has
been made, the plan to carry it out, the expectations,
roles and responsibilities, and arrangements for follow-
up. All encounters for informed shared decision
making should conclude with an action plan. This may
range from an informal verbal agreement to a formal
written contract.

Patient competencies
In the absence of good literature on communication
skills for patients, we asked our informants what
patients should be able to do to play their part in
informed shared decision making. The family physi-
cians found it difficult to identify specific skills that
patients should possess, but the patient educators and
patients (particularly those with chronic diseases) had
many suggestions, which we distilled into a preliminary
set of competencies (see box).

Patients who are active in managing their health
and illness are also active in managing the relationship
with their doctor. The patients with chronic
conditions confirmed that they learn how to engage in
partnership and improve their communication
through experience. Patients can be taught these skills
formally, although experiments have been piece-
meal. The refinement of patient competencies and
ways to teach them are major challenges for successful
implementation of informed shared decision making.

Other challenges
We have met three recurring objections in the course
of our work.

“IT would take too much time to do all that”
Several studies have shown that doctors trained in
some of these communications skills do not take
significantly longer to conduct patient interviews.
Encounter involving informed shared decision
making may take longer but may still be more efficient
because of improved health outcomes. Well developed
skills may permit time savings. These are research
questions. Our preliminary experiments with stand-
ardised patients (patients or actors trained to present
with a consistent history) and physicians willing and

Competencies for patients for informed shared decision making*

1 Define (for oneself) the preferred doctor-patient relationship
2 Find a physician and establish, develop, and adapt a partnership
3 Articulate (for oneself) health problems, feelings, beliefs, and expectations
   in an objective and systematic manner
4 Communicate with the physician in order to understand and share
   relevant information (such as from competency 3) clearly and at the
   appropriate time in the medical interview
5 Access information
6 Evaluate information
7 Negotiate decisions, give feedback, resolve conflict, agree on an action plan

*Preliminary list
able to practise informed shared decision making sug-
ggest that competence in such decision making can be
demonstrated in a 10 minute encounter.

“But we [physicians] already do that”
There is a wealth of somewhat depressing evidence that
physicians and patients do not communicate well.
Patients rarely give direct feedback about communica-
tion problems. This may encourage physicians to believe
that the studies do not apply to them personally. Skills in
communications and critical appraisal can be improved by
training. In our experience the use of standardised
patients with common problems has the advantage that
good communications are focused on improved health
outcomes, and physicians tend to be more accepting of,
and responsive to, feedback about communications from
patients (even standardised patients) than from peers or educators.

“What about patients who don’t want to be
involved?”
Specialist knowledge and the law create an imbalance in
the power relationship between physician and patient.
Any shift from a paternalistic physician practice toward a
“meeting between experts” requires the physician to encourage patient autonomy. Most
studies and theories of shared decision making are
illustrated by “hard cases”—that is, situations in which
decisions are for high stakes (such as treatment options for
cancer). If physicians and patients are to become
proficient at making informed and shared decisions it
would be sensible to begin with common problems.20
We are not surprised that patients shun making decisions about treatment for breast cancer if their
prior experience gave little opportunity or encourage-
mence in relatively minor medical situations.
Our informants noted the much commoner occurrence of elements of informed shared decision making in
eounters about chronic disease such as diabetes or
arthritis. Presumably, practice improved performance.
Social, cultural, and language factors may be bar-
riers to putting informed shared decision making into
practice, but these probably occur as serious problems
in only a minority of encounters for most physicians, and
possible solutions have been proposed.21 There are
many situations in which informed shared decision making
could be practised, in which patients wish it
were practised, and in which the major barriers are lack
of predisposition and skill.

This work was carried out in the Office of the Coordinator
of Health Sciences, University of British Columbia. We thank Ms
Astrid Richardson for help with conducting the interviews and
focus groups and the Canadian Cancer Society and Canadian
Diabetes Association for help in arranging the focus groups.
